Freeze drying; Sublimation; Designing sublimation system; Sublimation system; Infrared radiation.

ABSTRACT

Freeze drying is a process of separating water inside material (food) by changing its state directly from the solid state (ice) after freezing to vapor state in a low temperature and low-pressure environment, below the triple point O (0.0098°C, 4.58mmHg). Because the drying process is conducted in an absolute vacuum and heat transfer during the drying process is mainly radiation and conduction, while convection is not possible, so the drying time is prolonged, and energy is inefficient. Therefore, this study will calculate, design, and manufacture the DS-12 freeze drying system that provides heat for the freeze-drying process by using infrared radiation. When applying the optimal technological mode for freeze-drying: drying chamber’s temperature is 20.58°C; drying chamber’s pressure is 0.411 mmHg; drying time is 14.785 hours, results showed that energy costs per 1 kg of product reduced to a minimum of 4.75 kWh, saving nearly 25% of total energy costs as compared to the freeze-drying process using heat from conventional thermistors. The final product has very good quality, the loss of 10-HDA (freshness) after drying is only 0.65% and moisture of product is 4.22% (less than 4.5%) which meets the technological requirements. The results of this research can be fully applied to large scale production.

Figure 1. Phase diagram of water inside moist material during freeze-drying [3], [7]

1. Introduction
Freeze-drying is the process of dehydration from moist materials under low temperature and low pressure, below the triple point O (0.0098°C; 4.58mmHg). Temperature of moist material is below the crystallization point of water (less than 0°C), the drying pressure is less than 4.58mmHg. At that time, water from moist material transfer from solid state to vapor state directly [1]-[2].

Because the drying process is conducted in a low-pressure and low-temperature environment, products is completely qualified whereas none of previous methods could reach its quality. Protein is not hydrolysed, glucose is not gelatinized, lipids are not oxidized, vitamins, enzymes, biological active compounds are not destroyed, color and taste are almost preserved. The product has the highest porosity and reversibility as compared to other methods. In general, freeze-drying is one of the most effective ways to form products which its original quality could be maintained [1]-[3].

However, any method has its advantages and disadvantages. It can be noted that freeze-drying methods could create the best product quality. On the contrary, they consume a lot of energy than other methods and this can be explained by a complex process with various stages, as shown in figure 1:

- A→B: On the three-phase diagram at point A, the moisture of raw materials is initially in a liquid state, with a room temperature of 25°C and a pressure of 760mmHg (atmospheric pressure). Then, the process of freezing moist materials (thanks to the refrigeration system), changing moisture from a liquid state (point A) to a solid state (point B) where moisture must be completely freezeed. Therefore, the temperature at point B is the optimal temperature for moist materials due to the absolute crystallization of water inside (complete freezing) [3]-[5].

- B→C: The prerequisite for ice to sublimate is that the temperature and pressure of ice (freezing water) must be below the triple point O (0.0098°C; 4.58mmHg), as expressed in Figure 1. Thus, after being frozen at point B, the moist material is put into a freeze-drying chamber, then the vacuum pump is operated to transform the moist material from point B to point C in which point C has $P_C = P_{sub} < 4.58$mmHg. Because there will be an ice sublimation pressure corresponding to different ice temperature, as illustrated in Table 1 [3]-[5], pressure $P_C$ must also be determined at optimal conditions for the drying process to achieve the energy-efficient. Normally, point C is best located on the boundary line separating the solid phase and vapor phase. Nevertheless, due to hard conditions when operating and controlling the freeze-dryer system, it is difficult to control point C accurately on this boundary line.

$$T_{th}, ^\circ C \quad 0.0098 \quad 1.7 \quad 5.1 \quad 9.8 \quad 17.5 \quad 26.6 \quad 39.3 \quad 45.4 \quad 57.6 \quad 66.7$$

$$P_{th}, \text{mmHg} \quad 4.58 \quad 4.0 \quad 3.0 \quad 2.0 \quad 1.0 \quad 0.4 \quad 0.1 \quad 0.05 \quad 0.01 \quad 0.001$$

- C→D: This is the freeze-drying stage, moisture in the form of solid at point C (in a vacuum environment below the triple point) transfers directly to point D which is the vapor form, much energy needs to be consumed for the ice sublimation process [3]-[5].

As can be seen, it has been shown that the freeze-drying process always carried out in an absolute vacuum environment, heat transfer during the drying process is mainly radiation and conduction, while convection is not possible. On the other hand, freeze-drying systems often supply heat to the drying stage mainly by conduction, hence, the drying time is prolonged, energy costs are inefficient [5]-[7] as well as the price of final products increases, making it difficult to commercialize on market. Therefore, the research will be carried out the design and manufacture of a freeze-drying system (DS-12) which infrared radiation is used to supply heat for the process. This innovation will enhance the ability to transfer heat in a vacuum environment, combining with two other heating methods including conduction and radiation, it will shorten the drying time, maximize energy cost savings, create competitive benefits for products, and increase the potential investments for freeze-drying applications in the food production, food processing, and preservation of pharmaceutical products, etc.[5]-[7].

2. Method of calculating, designing and manufacturing the DS-12 freeze-drying system

2.1. The important initial parameters

- The drying material used in this study is royal jelly, the physical thermal parameters of the drying material and chemical compositions have been determined [4]-[5], [8]
The optimal drying technological mode of royal jelly has been determined [2], [4]-[5], [7]. It means that when conducting the drying process, energy costs are the lowest figure, moisture content meets the technological requirements, and the product is ensured in good standards.

- Productivity of freeze-drying system \( G_i \) (kg of material/batch), [7]
- Initial moisture of material \( W_i \) (%); The required moisture content of products is \( W_e \) (%) [7].
- Drying time per batch is \( \tau \) (h), [7].
- The drying process always has 3 stages: stage 1 is freezing; stage 2 is freeze-drying and stage 3 is vacuum drying (if any) [2].
- The DS-12 freeze-drying system has the ability to self-freeze, so the freezing chamber is also the drying chamber, [7].

2.2. Scientific basis for calculation and design

2.2.1. Calculate the freezing system to freeze raw materials in stage 1

- **Calculate the size of the freezing chamber** [4], [6], [8]
  - Number of trays containing raw materials in the freezing chamber:
    \[
    N_k = \frac{G_i}{g_k}
    \]  
    \((1)\)

    In which: \( N_k \) – is the number of trays; \( g_k \) (kg/tray) - is the mass of the raw material. Each tray has three dimensions including width of 250mm, length of 300mm and height of 30mm.
  - Number of shelves for laying materials as well as transferring heat for the drying process in the freezing chamber:
    \[
    N = \frac{N_k}{n_k}
    \]  
    \((2)\)

    With: \( n_k \) – is the number of trays in each shelf; \( N \) – is the number of shelves for laying materials as well as transferring heat for the drying process in the drying chamber; \( n_k = a \times b \), \( a \) are the number of trays arranged according to width and \( b \) is the number of trays arranged according to length.
  - Determine the width of the freezing chamber:
    \[
    R = 0.2 \times b + 2 \times \delta, \text{ m}
    \]  
    \((3)\)
  - Determine the length of the freezing chamber:
    \[
    D = 0.4 \times a + 2 \times \delta, \text{ m}
    \]  
    \((4)\)
  - Determine the height of the freezing chamber:
    \[
    H = (h + 1) \times N + 2 \times \delta, \text{ m}
    \]  
    \((5)\)

    With \( \delta \) (m) – is the distance between the top/bottom drying tray to the wall of the drying chamber (\( \delta = 0.005 \text{ m} \)); \( h \) (m) is the distance between two heat transfer shelves (usually chosen \( h = 0.012 \pm 0.015 \text{ m} \)).
  - Determine the volume of the drying chamber:
    \[
    V = R \times D \times H, \text{ m}
    \]  
    \((6)\)

- **Calculate the cooling capacity of the refrigeration compressor** [4], [6], [8]

    The cooling capacity of the refrigeration compressor for the freezing chamber is determined according to equation (7), (Dzung NT, 2012 & 2013):
    \[
    Q_\text{Comp} = \left( \frac{Q_p + Q_{\text{tray}} + Q_{\text{air}}}{\tau} + Q_{\text{env}} + Q_{\text{overh}} \right) \times k_s, \text{ kW}
    \]  
    \((7)\)

    In which: \( Q_p \) (kJ) - refrigeration cost of the freezing process; \( Q_{\text{tray}} \) (kJ) - heat output from the tray containing materials; \( Q_{\text{air}} \) (kJ) - heat removed to cool the air in the freezing chamber; \( Q_{\text{env}} \) (kW) - heat removed to cool the environment; \( Q_{\text{overh}} \) (kJ) - heat removed to cool the heating plate and shelf.
from the environment penetrating through the wall of the freezing chamber; \( Q_{overh} \) (kW) - environmental heat entering the pipeline to superheat the steam to the compressor; \( \tau(s) \) - freezing time for a batch; \( k_s \) – safe load factor.

- **Build the operating cycle of the refrigeration system in stage 1** [4], [6], [8]

The refrigeration system used to freeze moist materials in stage 1 before freeze-drying is a two-stage compression refrigeration system (see Figure 2), the refrigerant used in this system is R404A.

**Table 2. State parameters of the two-stage compression refrigeration cycle using R404A**

**Figure 2. P-h graph of R404A**

- **Calculate the level 1 compressor** [4], [6], [8]

- Mass flow (\( m \), kg/s) and volume flow (\( V_{1p} \), m\(^3\)/s) of refrigerant R404A circulating through the level 1 compressor:
m_1 = \frac{Q_{Comp}}{h_1-h_8}, \text{ kg/s} \quad \text{and} \quad V_{1p} = m_1 \times v_{1i}, \quad \text{m}^3/\text{s} \quad (8)

- Suction capacity (\lambda_1) of the level 1 compressor:

\lambda_1 = \lambda_{1w} \times \lambda_{1i} = \left( \frac{T_0}{T_M} \right) \times \left\{ \frac{P_0-\Delta P_0}{P_o} - C \left[ \left( \frac{P_M+\Delta P_M}{P_o} \right)^{1/n} - \frac{P_0-\Delta P_0}{P_o} \right] \right\} \quad (9)

In which: \( P_M = \sqrt{P_o \times P_k}, \) bars; \( C = 0.03 \pm 0.05 \) dead space coefficient; \( P_0, P_M, P_k \) (bar) are the refrigerant’s evaporation pressure, intermediate pressure and refrigerant’s condensation pressure.

- Theoretical suction volume flow of the level 1 compressor (\( V_{1th}, \text{ m}^3/\text{s} \)):

\[ V_{1th} = V_{1p} / \lambda_1, \text{ m}^3/\text{s} \quad (10) \]

- Adiabatic compressor capacity (\( N_{1s}, \text{ kW} \)) and indicated compressor capacity (\( N_{1i}, \text{ kW} \)) of the level 1 compressor:

\[ N_{1s} = m_1 \times (h_2 - h_1'), \text{ kW} \quad \text{and} \quad N_{1i} = N_{1s} / \eta_1i, \text{ kW} \quad (11) \]

- Friction capacity (\( N_{1ms}, \text{ kW} \)) and effective capacity (\( N_{1es}, \text{ kW} \)) of the level 1 compressor

\[ N_{1ms} = P_{1ms} \times V_{1p} / 10^3, \text{ kW and} \quad N_{1e} = N_{1ms} + N_{1i}, \text{ kW} \quad (12) \]

- Electrical capacity (\( N_{1el}, \text{ kW} \)) and electric motor capacity (\( N_{1mc}, \text{ kW} \)) of the level 1 compressor:

\[ N_{1el} = \frac{N_{1i}}{\eta_{itr} \times \eta_{1el}}, \text{ kW} \quad \text{and} \quad N_{1mc} = k_1 \times N_{1el}, \text{ kW} \quad (13) \]

In which: parameters of the level 1 compressor include: \( \eta_1i \) is the performance indicator; \( P_{1ms} (\text{N/m}^2) \) is the friction pressure; \( \eta_{itr} \) is the transmission efficiency; \( \eta_{1el} \) is the effective performance; \( k_1 \) is the safe load factor for the motor of the level 1 compressor.

- **Calculate the level 2 compressor** [4], [6], [8]

- Mass flow (\( m_2, \text{ kg/s} \)) and volume flow (\( V_{2p}, \text{ m}^3/\text{s} \)) of refrigerant R404A circulating through the level 2 compressor:

\[ m_2 = m_1 \times \frac{h_2-h_8}{h_3-h_5}, \text{ kg/s} \quad \text{and} \quad V_{2p} = m_2 \times v_{2i}, \text{ m}^3/\text{s} \quad (14) \]

- Suction capacity (\( \lambda_2 \)) of the level 2 compressor:

\[ \lambda_2 = \lambda_{2w} \times \lambda_{2i} = \left( \frac{T_M}{T_k} \right) \times \left\{ \frac{P_M-\Delta P_M}{P_M} - C \left[ \left( \frac{P_k+\Delta P_k}{P_M} \right)^{1/n} - \frac{P_M-\Delta P_M}{P_M} \right] \right\} \quad (15) \]

- Theoretical suction volume flow of the level 2 compressor (\( V_{2th}, \text{ m}^3/\text{s} \)):

\[ V_{2th} = V_{2p} / \lambda_2, \text{ m}^3/\text{s} \quad (16) \]

- Adiabatic compressor capacity (\( N_{2s}, \text{ kW} \)) and indicated compressor capacity (\( N_{2i}, \text{ kW} \)) of the level 2 compressor:

\[ N_{2s} = m_2 \times (h_4 - h_3), \text{ kW} \quad \text{and} \quad N_{2i} = N_{2s} / \eta_2i, \text{ kW} \quad (17) \]

- Friction capacity (\( N_{2ms}, \text{ kW} \)) and effective capacity (\( N_{2e}, \text{ kW} \)) of the level 2 compressor:

\[ N_{2ms} = P_{2ms} \times V_{2p} / 10^3, \text{ kW and} \quad N_{2e} = N_{2ms} + N_{2i}, \text{ kW} \quad (18) \]

- Electrical capacity (\( N_{2el}, \text{ kW} \)) and electric motor capacity (\( N_{2mc}, \text{ kW} \)) of the level 2 compressor:
\[ N_{2el} = \frac{N_{2e}}{\eta_{2tr} \times \eta_{2el}}, \text{ kW} \]  \hspace{1cm} \text{and} \hspace{1cm} N_{2m} = k_2 \times N_{2el}, \text{ kW} \]  
\hspace{1cm} (19) 

In which: parameters of the level 2 compressor include: \( \eta_{2e} \) is the performance indicator; \( P_{2m} \) (N/m²) is the friction pressure; \( \eta_{2tr} \) is the transmission efficiency; \( \eta_{2el} \) is the effective performance; \( k_2 \) is the safe load factor for the motor of the level 2 compressor.

- Total electric motor capacity (\( N_m, \text{ kW} \)) of the 2 stage compressor:
\[ N_m = N_{1m} + N_{2m}, \text{ kW} \]  
\hspace{1cm} (20) 

- **Calculate the R404A refrigerant condenser** [4], [7]
\[ F_{\text{in}} - \text{cond} = \frac{Q_{\text{condenser}}}{q_{\text{in-cond}}} = \frac{m_2 \times (h_4 - h_5) + (N_{2i} - N_{2s}) \times 10^3}{q_{\text{in-cond}}} \text{, m}^2 \]  
\hspace{1cm} (21) 

With: \( Q_{\text{condenser}} \) (kW) is the heat released by the refrigerant; \( F_{\text{in}} - \text{cond} \) (m²) is the inner wall of heat exchange area in the condenser; \( q_{\text{in-cond}} \) (W/m²) is the heat flow density of the condenser.

- **Calculate intermediate cooler** [4], [7]
\[ F_{\text{in}} - \text{inter} = \frac{Q_{\text{inter}}}{q_{\text{in-inter}}} = \frac{m_1 \times (h_5 - h_7) \times 10^3}{q_{\text{in-inter}}} \text{, m}^2 \]  
\hspace{1cm} (22) 

With: \( q_{\text{in-inter}} \) (W/m²) is the heat flow density of the intercooler; \( Q_{\text{inter}} \) (kW) is the heat load of the intercooler; \( F_{\text{in}} - \text{inter} \) (m²): heat exchange area of the intercooler.

2.2.2. **Calculate the freeze-drying system to dry materials in stage 2 and 3**

- **Calculate the heat load of the sublimation chamber** [4], [7]
- The amount of water separated from the moist material during the drying process:
\[ W = G_i \left( \frac{W_t - W_e}{100 - W_e} \right), \text{ kg/s} \]  
\hspace{1cm} (23) 

In which: \( W_t, W_e \) (%) are the moisture content of raw materials and products; \( W \) (kg/s) is the amount of moisture dehydrated during the drying process; \( \tau_{\text{sub}} = \tau_2 + \tau_3 \) is the total time of the drying process; \( \tau_2(s) \) : time of stage 2 of the freeze drying; \( \tau_3(s) \) : time of stage 3 of the low temperature vacuum drying.

- Heat released during the drying process in stage 2 and 3:
\[ Q_{\text{chamber-sub}} = Q_{\text{sub}} + Q_{\text{vacuum}} - Q_{\text{env}}, \text{ kW} \]  
\hspace{1cm} (24) 

With: \( Q_{\text{sub}} = r_{\text{sub}} \times W_{\text{sub}} \) (kW) is the heat for the second stage of freeze drying; \( Q_{\text{vacuum}} = r_{\text{vac}} \times W_{\text{vac}} \) (kW) is the heat consumed for stage 3 of low-temperature vacuum drying; 
\[ Q_{\text{env}} = K \times F_2 \Delta \tau \times 10^{-3} \] (kW) is the environmental heat entering the drying chamber; \( Q_{\text{chamber-sub}} \) (kW) is the freeze-drying chamber’s heat; \( r_{\text{sub}} \) (kJ/kg) is the latent heat of sublimation of water; \( r_{\text{vac}} \) (kJ/kg) is the latent heat of vaporization of water; \( W_{\text{sub}} \) (kg/s) is the amount of moisture sublimated in stage 2; \( W_{\text{vac}} \) (kg/s) is the amount of moisture evaporated in stage 3; \( W \times \tau = W_{\text{sub}} \times \tau_2 + W_{\text{vac}} \times \tau_3 \).

- Radiant heat exchange area of the freeze-drying chamber:
\[ F_{\text{chamber-sub}} = \frac{Q_{\text{chamber-sub}}}{k \times C_0 \times e_{\text{ref}} \times \left[ \frac{T_{\text{shelf}}}{100} \right]^4 - \left[ \frac{T_{\text{material}}}{100} \right]^4}, \text{ m}^2 \]  
\hspace{1cm} (25) 

With: \( T_{\text{shelf}} \) (K) is the radiation panel’s temperature; \( T_{\text{material}} \) (K) is the temperature of materials during the freeze-drying process; \( k = 1.2 \); \( e_{\text{ref}} = 0.8768 \) is the reference blackness; \( C_0 = 5.67 \text{ W/(m}^2\text{K}^4) \) is the radiation coefficient of an absolute black object; (Dzung NT, 2017)

- The number of infrared light bulbs for the freeze-drying chamber:
With: \( z \) is the number of infrared bulbs; \( p \) (kW/bulb) – Radiant power emitted by each bulb

- **Calculate the condenser** [4], [7]

The heat load of the condenser is determined according to equation (26)

\[
Q_{\text{comp}}^\text{[con–fre]} = Q_1 + Q_2 + Q_3 + Q_{\text{env1}}, \text{ kW}
\]  

\( Q_1 = W \times C_{ph} \times (t_{\text{ste}} - t_w), \text{ kW} \) is the amount of heat removed to condense steam; \( Q_2 = W \times r_{\text{cry}} \) (kW) is the amount of heat removed to freeze the steam after condensation; \( Q_3 = W \times (t_w - t_{\text{ice}}) \times C_{pw} \) (kW) is the amount of heat removed to lower the water’s temperature after freezing; \( Q_{\text{env1}} = K_{\text{cond-cry}} \times F_{\text{cond-cry}} \times \Delta t_{\text{cond-cry}} \) (kW) is heat from the environment; \( r_{\text{cry}} \) (kJ/kg): latent heat of freezing of water; \( t_{\text{ste}} \) (°C) is the temperature of steam releasing from the drying chamber, \( t_w \) (°C) is the condensation temperature of steam and \( t_{\text{ice}} \) (°C) is the freezing temperature of water from the drying chamber to the condenser.

- **Heat exchange area of the condenser** [4], [7]

\[
F_{\text{cond-cry}} = \frac{Q_{\text{comp}}^\text{[con–fre]}}{q_{\text{w.tr}[\text{con–fre}]}, \text{ m}^2}
\]  

\( F_{\text{cond-cry}} \) (m²) is the heat exchange area of the condenser; \( Q_{\text{comp}}^\text{[con–fre]} \) (kW) is the load of the condenser; \( q_{\text{w.tr}[\text{con–fre}]} \) (W/m²) is the heat flow density of the condenser.

- **Calculate the refrigeration system for the condenser** [4], [7]

The cooling capacity of the refrigeration compressor running for the condenser is determined according to equation (29):

\[
Q_{\text{comp}}^\text{[con–fre]} \leq Q_{\text{comp}}^\text{[con–fre]}, \text{ kW}
\]  

When the conditions in equation (28) are satisfied, according to research by Dzung NT (2017), the refrigeration system used for the freezing of moist materials in stage 1 will be compatible for use in the condenser, hence it will improve the economic efficiency for DS-12 freeze-drying system’s manufacture.

- **Productivity** \((N_p, \text{ m}^3/\text{s})\) **of vacuum pump** [4], [7]

\[
N_p = k_1 \times k_2 \times \frac{V}{\tau_d} \ln \left( \frac{B - P_{\text{limit}}}{P_{\text{sub}} - P_{\text{limit}}} \right), \text{ m}^3/\text{s}
\]  

\( V \) (m³) is the volume of the freeze-drying chamber, \( k_1 \) is the safety factor and \( k_2 \) is the leakage coefficient of the freeze-drying chamber; \( B \) (N/m²) is the atmospheric pressure; \( P_{\text{sub}} \) is the freeze-drying chamber pressure; \( P_{\text{limit}} \) is the minimum pressure of the vacuum pump; \( \tau_d \) (s) is the time to lower the pressure from \( B \) to \( P_{\text{sub}} \) in the drying chamber, Dzung NT (2012).

- **Defrosting time for the condenser after a batch** [4], [7]

\[
\tau_{\text{defrost}} = \frac{Q_{\text{defrost}}}{K \times F \times \Delta t_a} \times \frac{10^3}{60}, \text{ min/batch}
\]  

In which: \( F \) (m²) is the outer surface area; \( Q_{\text{defrost}} \) (kW) is the heat to melt frozen water; \( \Delta t_a \) (°C) is the logarithmic temperature difference; \( K \) (W/(m²K)) is the heat transfer coefficient of the device; \( \tau_{\text{defrost}} \) (minute) is the defrosting time for one batch.

2.3. Method of designing and manufacturing the freeze-drying system

2.3.1. Designing method
Data will be obtained after calculating the mass balance and energy balance of the freeze-dryer. Thanks to this data set, design drawings will be constructed to serve the manufacturing process. In this study, Autocad 2024 software was used to design and create technical drawings, [4], [6], [7].

2.3.2. Manufacturing method

The following mechanical processing methods are used: bending, pressing, lathing, milling, or welding etc. to accurately fabricate the freeze-drying system according to the initially calculated data set, [4], [6], [7].

2.4. Method to evaluate the quality of the freeze-drying system.

Determination of chemical composition of royal jelly is presented in [3]
Experimental methods need to be conducted from raw materials to creating products in order to evaluate the operation and quality of the new freeze-drying system, the energy cost for 1 kg of product obtained from this freeze-dryer as well as the product moisture and product quality [7].

To simplify the assessment, experiments can be carried out immediately after the manufacture of the freeze-drying system, following by these parameters: the energy cost $y_1$ (kWh/kg), the moisture content of the product $y_2$ (%), recovery capacity $y_3$ (%) [2], [3], [5].

3. Results and discussion

3.1. Determine the initial parameters for calculation and design.

In this study, royal jelly was used as the raw material. Royal jelly was analysed for its chemical compositions at laboratory B209, Ho Chi Minh City University of Technology and Education, and the results were summarized in Table 3.

Through experiments, the vital thermophysical parameters had also been determined for calculating and designing the DS-12 freeze-drying system – which integrates the self-frozen and infrared radiation heating functions. Results were presented in table 4.

In this study, the DS-11 freeze-drying system, providing heat by a resistor, was used to build a model for describing the simultaneous royal jelly freeze-drying process, along with the experimental freeze-drying of royal jelly was carried out, then the multi-objective optimization problems were established and solved. The results had established the optimal freeze-drying modes in Table 5, this means that when conducting the royal jelly drying process, the product would have the best quality, the required moisture content and energy costs would be reduced to the lowest level. Data in table 5 were considered to be the basis for calculating and designing the DS-12 freeze-drying system, which infrared radiation is use for heating purpose during the freeze-drying process.

| Stage 3: low temperature vacuum drying | Drying time | τ_3, (h) | 0.000 |
| Energy costs for 1 kg of freeze-dried royal jelly | q_3 (kWh/kg) | 0.00 |

Total time of freeze-drying process: \( τ = τ_1 + τ_2 + τ_3 \) (h) | τ (h) | 19.913 |

3.2. Establish the principal diagram of the DS-12 freeze-drying system.

The productivity of the drying system \( G_i \) (kg of material/batch), the drying time of each batch is \( τ(h) \) were supposed to use for calculating and designing the DS-12 freeze-dryer which has the self-frozen and infrared radiation heating modes integrated inside the system, as demonstrated in Table 5.

Due to the freezing ambient temperature \( T_{env-fr} = -40.46^\circ C \), the evaporation temperature of the refrigerant used for the refrigeration system needed to be \( T_0 = T_{env-fr} - ΔT_0 = -50^\circ C \) and refrigerant condensation temperature \( T_k = T_{env-air} + ΔT_k = 33 + 7 = 40^\circ C \) for design.
At this point, research needs to choose a refrigerant that is suitable for the evaporation temperature $T_0 = -50^\circ C$ and the condensation temperature of the refrigerant is $T_k = 40^\circ C$. Therefore, the refrigerant applied for this system is R404A - a new and friendly refrigerant permitted by the world’s environmental protection organisation.

Looking up the $lgP - h$ graph of refrigerant R404A: the value of $T_0 = -50^\circ C$ corresponds to $P_0 = 0.851$ bar; the value of $T_k = 40^\circ C$ corresponds to $P_k = 18.148$ bar. Thus, the compression ratio was determined: $\beta = P_k/P_0 = 18.148/0.851 = 21.325 > 9$ (see Table 2). Because the compression ratio $\beta$ is greater than 9, it is possible to use the two stage refrigeration compressor or more. In this study, a two stage refrigeration compressor was chosen with the principle diagram in Figure 3.

### 3.3. Calculation and design of the DS-12 freeze dryer system

Based on Table 3, Table 4, Table 5 and principle diagram of DS-12 self-frozen freeze-drying system was established in Figure 3, methods for calculation and design described in section 2 were applied, hence the results are shown in Table 6.

### 3.4. Manufacturing the DS-12 freeze-drying system

![Image of DS-12 freeze-drying system]

Results of calculation and design were summarized in Table 6. AutoCAD 2024 software was used to create the necessary technical drawings for manufacturing.

After being created by AutoCAD 2024 software, technical drawings were transferred to the mechanical machine systems described in section 2.3 to manufacture the freeze-dryer. The DS-12 freeze-drying system which has self-frozen function and infrared radiation heating function for the freeze-drying process were completed and shown in Figure 4. Its technical parameters are below:

- Maximum equipment productivity: 10 kg of material/batch.
- The temperature of the freezing environment in stage 1 can be adjusted: -40⁰ to -45⁰C.
- The temperature of the sublimation drying chamber in stages 2 and 3 can be adjusted: 0⁰ to 80⁰C.
- The temperature of the condenser is adjustable: -45⁰ to 25⁰C.
- The pressure of the sublimation drying chamber in stages 2 and 3 can be adjusted: 0.005 to 1.00 mmHg.
- Automatic measuring equipment are controlled by a program on a computer.

### 3.5. Experiments to assess the stability and quality of the DS-12 freeze-drying system

By using the optimal parameters presented in Table 5 for royal jelly’s freeze-drying process, experiments were conducted on the new self-frozen DS-12 freeze-drying system using heat from infrared radiation (Figure 4). After drying, royal jelly products were analysed and evaluated in terms of freeze-drying time, energy costs for 1 kg of freeze-dried royal jelly product, the moisture content of the
final product and the loss of 10-HDA (freshness). Next, products would be compared to the other which was dried on the DS-11 freeze-drying system heated by a resistor. Results were expressed in Table 7.

As can be seen from Table 7, the DS-12 freeze-drying system which heat supply for the freeze-drying process is infrared radiation (Figure 3), operated steadily. Freeze-dried royal jelly products were of good quality, the loss of 10-HDA (freshness) after drying was only 0.65%. As compared to products drying on the DS-11 system which provides heat for the freeze-drying process by conventional method, loss of 10-HDA (freshness) after drying was 0.78%. Thus, drying on the DS-12 freeze-drying system had resulted in better quality products.

<tr>
<td>Total time of freeze drying process: $\tau = \tau_1 + \tau_2$ (h)</td>
<td>16.415</td>
<td>19.913</td>
<td></td>
</tr>
</tbody>
</table>
The moisture content of products drying on DS-11 freeze-drying system was 4.19% while this figure on the DS-12 freeze-drying system was 4.22%. Both results were less than 4.5% (standard of moisture content in freeze-dried products) so drying on the DS-11 and DS-12 freeze-drying systems meets the technological requirements. However, to achieve the required product’s moisture of less than 4.5%, the drying time on the DS-12 freeze drying system took 16.415 hours, whereas the DS-11 freeze-drying system took quite a long time of 19.913h.

Due to the long drying time, drying on the DS-11 freeze-drying system consumed more energy than the other. Results in Table 7 also illustrated that if materials were dried on the DS-12 freeze drying system, the energy consumed would be 4.75 kWh/kg of product while it would be 6.32 kWh/kg of product on the DS-11 freeze-drying system.

Obviously, calculations showed that if freeze-drying process applied infrared radiation heating, energy costs would be saved from 20% to 25% as compared to the system using conventional heat. Therefore, the DS-12 freeze-drying system using infrared radiation for heating had been successfully manufactured and could be immediately put into practice to save production costs. The products also had good quality and required moisture content.

4. Conclusions

This research had successfully manufactured a DS-12 freeze-drying system which infrared radiation is apply for heating and maximum equipment capacity was 10 kg of material/batch; The temperature of the freezing environment in stage 1 can be adjusted: -45 °C - -40°C; The temperature of the freeze-drying chamber in stage 2 and 3 can be adjusted: 0°C-80°C; The temperature of the condenser is adjustable: -45 °C - -25°C; The pressure of the freeze-drying chamber in stages 2 and 3 can be adjusted: 0.005 - 1.00 mmHg; This system automatically measured and controlled by computer programming. The DS-12 freeze-drying system with the infrared radiated heating function operated with the optimal technological parameters: The temperature of the freeze-drying chamber was 20.58°C; The freeze-drying chamber pressure was 0.411 mmHg; The duration of the drying process was 14.785 hours (excluding the first freezing period). Experimental results showed that products had completely qualified, the loss of 10-HDA (freshness) after drying was only 0.65%, the moisture content of products was 4.22% (less than 4.5% that meets technological requirements), energy costs were reduced to a minimum of 4.75 kWh/kg of product, saving nearly 25% as compared to the previous freeze-drying system which supplies heat for the drying process by conventional thermostirs.
